PSG INSTITUTE OF MEDICAL SCIENCE & RESEARCH

Abstract: INTRODUCTION Sputum microscopy remains the mainstay of diagnosis of pulmonary tuberculosis but lacks sensitivity compared to culture. Pre-requisite for microscopic examination of sputum sample is prior decontamination. Conventional methods for decontamination include Petroffs method which is routinely done, while N-Acetyl-L-Cysteine Sodium Hydroxide (NALC-NaOH) still remains a gold standard. OBJECTIVES To evaluate the performance of the Novel Hypertonic Saline Sodium hydroxide (HS-SH) method with the standard NALC-NaOH for decontamination of sputum specimens. MATERIALS AND METHODS Total of 143 sputum samples obtained from both in-patients and out-patients of PSG Hospitals were subjected to decontamination by both HS-SH method and NALC-NAOH methods. Slides were then examined under oil immersion for acid fast bacilli by conventional Ziehl Neelsen staining method.

RESULTS Out of 143 microbiological sputum samples, 104 were found to be positive for acid fast bacilli by both Modified petroffs method and Hypertonic saline sodium hydroxide method (HS-SH) of concentration and decontamination and 39 samples were negative by both these methods. Sensitivity, Specificity, Positive predictive value Negative predictive value of the HS-SH method was found to be 100. CONCLUSION The novel HS-SH decontamination method is equally sensitive, specific, cost-effective, feasible and less time consuming compared to the gold standard NALC-NaOH method for decontamination of Mycobacterium tuberculosis from sputum samples and can be routinely used in all peripheral health centres because of the low cost, especially in developing countries. Keyword: Novel HS-SH Sputum concentration method for Tuberculosis
INTRODUCTION:
Sputum microscopy remains the mainstay of diagnosis of pulmonary tuberculosis but lacks sensitivity compared to culture. Pre-requisite for microscopic examination of sputum sample is prior decontamination. Conventional methods for decontamination include Petroff’s method which is routinely done, while N-Acetyl-L-Cysteine Sodium Hydroxide (NALC-NaOH) still remains a gold standard.

NEED FOR THE STUDY:
Tuberculosis caused by Mycobacterium tuberculosis (or Koch’s bacillus) even though curable and preventable it is still one of the leading infectious cause of morbidity and mortality especially in developing countries like India. Global incidence of tuberculosis is 9.4 million cases annually, whereas India accounts for 2.0 million i.e., one-fifth of the Global incidence (2010). The Global prevalence rate is 3.8 million bacteriologically positive cases (2000) with death rate of 3,25,000 per year due to TB. In India the prevalence rate is 249 per lakh population (2009). The life time risk of a person developing Tuberculosis is 10% (10 out of 100). Diagnosis of Tuberculosis is by a combination of proper history taking, clinical examination, Microbiological evaluation by Sputum microscopy and Culture (Conventional or automated) which is the gold standard and also by correlation with roentgenologic examination. Resistance in Tuberculosis had become a global menace for treating physicians. N-Acetyl-L- Cysteine method has 4% NaOH and kills 60-70% of Mycobacteria, and the sensitivity for acid fast smear is 66.7%. Hypertonic Saline-Sodium Hydroxide (HS-SH) method has only 1.33% NaOH is used for decontamination. Relative Centrifugal Force for HS-SH method is high (4000rpm) and the sensitivity for acid fast bacilli smear is about 71.4% which is more than the N-acetyl-L-cysteine-Sodium hydroxide decontamination and concentration method. Concentrated sputum techniques are much better than direct sputum microscopy and Modified Petroff’s method is the widely used DC method but this method is too cumbersome to carry in field locations. There is only one report to say that Hypertonic Saline Sodium Hydroxide(HS-SH) method of decontamination is superior to gold standard NALC-NaOH method in India. So, we would like to evaluate Hypertonic Saline Sodium Hydroxide(HS-SH) method for decontamination of sputum samples for sputum microscopy.

REVIEW OF LITERATURE:
Diagnostic methods available to detect tuberculosis are Direct approach is by Microscopy, Culture, Biochemical test, Nuclear techniques. In developing countries diagnosis of acid fast bacilli is performed by microscopic examination of Ziehl-Neelsen (ZN) stained sputum smear, because it is simple, inexpensive and it provides rapid results. But this technique has a low sensitivity 22-43% for single smear. And also up to 60% underoptimal conditions, when compared with cultures so that culture remains as gold standard to diagnose tuberculosis. The threshold for detection of acid fast bacilli in sputum samples under optimal condition is between 10^{4}-10^{5} bacilli/ml, which can be obtained by decontamination & concentration techniques. Various decontamination methods used for decontamination of sputum samples for Mycobacterium tuberculosis are Bleach(6% NaOCl) method, Petroff’s method, Modified Petroff‘s Sodium Hydroxide method, N-Acetyl-L-Cysteine-sodium Hydroxide method (
NALC - NaOH), Hypertonic Saline Sodium Hydroxide (HS-SH) method, Zephiran-Trisodium Phosphate (Z-TSP) method, Oxalic Acid method, Sulphuric Acid method, Cetylpyridinium chloride-sodium chloride (CPC) method. In hypertonic saline-NaOH method, hypertonic saline is used for mucleolysis and Sodium hydroxide for decontamination. Literature survey has shown HS-SH technique substantially increased the sensitivity of AFB smears compared with the routine direct smear for AFB and correlated well with the NALC-NaOH decontamination method for sputum culture in suspected Tuberculosis patients. Hypertonic saline has been used successfully for the symptomatic treatment of cystic fibrosis.

**OBJECTIVES:**
To evaluate the performance of the Novel Hypertonic Saline Sodium hydroxide (HS-SH) method with the standard NALC-NaOH for decontamination of sputum specimens.

**MATERIALS AND METHODS:**
Total of 143 sputum samples obtained from both in-patients and outpatients of PSG Hospitals were subjected to decontamination by both HS-SH method and NALC-NAOH methods. Slides were then examined under oil immersion for acid fast bacilli by conventional Ziehl Neelsen staining method.

**INCLUSION CRITERIA:**
Patients with cough more than 2 weeks and/or blood stained sputum.

New sputum positive pulmonary tuberculosis patients before initiation of treatment.

**EXCLUSION CRITERIA:**
2. Inadequate sample volume (< 2ml).
3. Sample not representative of lower respiratory tract.
4. Patient denying to participate in the study.

**DECONTAMINATION METHOD:** Procedure for Hypertonic Saline - Sodium Hydroxide Method (HS-SH):

One ml portion of sputum was mixed with one ml 7 % (w/v) NaCl and one ml 4 % (w/v) NaOH in a sterile 15 ml centrifuge tube (BD Falcon) and homogenized for 15–20 s using a vortex mixer [final concentrations (w/v) in 3 ml: 2.33 % NaCl, 1.33 % NaOH]. The tubes were then incubated at 37 uC for 30 min. After incubation, the mixture was neutralized with sterile PBS (pH 6.8), bringing the total volume to 15 ml. The mixture was vortexed for 5 s and then centrifuged at 3400 g for 15 min at 15 uC, using aerosolproof shields. The supernatant was discarded into a splash-proof container with a tuberculocidial solution. The procedure used has been described previously and is recommended by the Centers for Disease Control and Prevention and the WHO/IUATLD. Briefly, one ml sputum was added to a 50 ml BD Falcon centrifuge tube with one ml of solution containing 0.5 % (w/v) NALC, 2.67 % (w/v) NaOH and 1.45 % (w/v) sodium citrate and mixed well (final concentrations (w/v) in 2 ml: 0.25 % NALC, 1.34 % NaOH, 0.73 % sodium citrate). The tubes were incubated at room temperature for 15 min.
After incubation, the mixture was neutralized with PBS, bringing the total volume to 50 ml. The rest of the procedure was as described above. **ZN sputum Smear preparation:** AFB sputum smear preparation done in Biosafety cabinet level II. One drop of each suspended pellet was used to prepare slides for AFB microscopy using the Ziehl–Neelsen stain. Each slide was coded, read blindly by a qualified technician and reported according to the NTP and WHO/ IUATLD standards (WHO, 1998). Smears were reported as follows: +, 1–9 AFB in 100 microscopic fields (few bacilli); 1+, 10–99 AFB in 100 fields; 2+, 1–10 AFB per field in at least 50 fields; 3+, more than 10 AFB per field in at least 20 fields. Each slide will be coded, examined and graded according to the RNTCP guidelines.

**RESULTS:**
Out of 143 microbiological sputum samples, 104 were found to be positive for acid fast bacilli by both Modified petroff’s method and Hypertonic saline sodium hydroxide method (HS–SH) of concentration and decontamination and 39 samples were negative by both these methods. Sensitivity, Specificity, Positive predictive value & Negative predictive value of the HS–SH method was found to be 100%.

**DISCUSSION:**
Decontamination methods for sputum microscopy for diagnosis of tuberculosis presently used are cumbersome, time consuming and expensive. Better methods are needed particularly developing countries. According to the study conducted by Christian A. Ganoza et al, the sensitivity for acid-fast bacilli (AFB) smears had increased from 28.6% using the direct method to 71.4% Hypertonic Saline Sodium Hydroxide (HS–SH) method and 66.7% N-Acetyl-L-Cysteine (NALC-NaOH) using decontamination (DC) methods. In a study conducted in India by Sushil Kumar Chaudary et al, sensitivity of NALC-NaOH and HS–SH methods were 46% and 52% respectively. The proposed novel HS–SH DC method improved the sensitivity of AFB microscopy compared with a routine direct smear; its performance was comparable to that of the Modified Petroff’s method for AFB smears, but it was methodologically simpler and less expensive, equally sensitive and can be adopted in National TB control programme especially in developing countries.
Sensitivity, Specificity, Positive predictive value & Negative predictive value of the HS-SH method was found to be 100% which is comparable with the standard Modified petroff’s method. Novel HS-SH method was not all cumbersome compared to the gold standard NALC-NaOH method.

CONCLUSION:
The novel HS-SH decontamination method is equally sensitive, specific, cost-effective, feasible and less time consuming compared to the gold standard NALC-NaOH method for decontamination of Mycobacterium tuberculosis from sputum samples and can be routinely used in all peripheral health centres because of the low cost, especially in developing countries.
