Abstract

Introduction: Ventricular septal defect (VSD) is the most common congenital cardiac anomaly that may occur as an isolated anomaly or as a part of complex of anomaly such as tetralogy of Fallot. Small defects may close spontaneously and may cause no significant disability in lifetime.

Materials and Methods: This is a comparison study of interrupted and continuous suture technique for closure of VSDs done with the objective to study the experience regarding the effectiveness, post-operative complication rates, and the total outcome done in the Department of Cardiothoracic Surgery, Government Rajaji Hospital from October 2012 to December 2015.

Results: A total of 43 total s were recruited for the study. Of these, 18 had VSD repair using glutaraldehyde-treated autologous pericardial patch and 25 had VSD repair using Gore-Tex patch. The majority of patients were in the age group of 6-10 years comprising 44% of the total study. Children under 5 years of age comprised <10% of the study group. The most common associated anomaly was congenital mitral valve abnormality, mainly cleft mitral valve and chordal prolapsed leading to significant mitral regurgitation requiring mitral valve repair. Right ventricular outflow tract obstruction was due to hypertrophied RV muscle bundle which required the division of the muscle bundle to relieve the obstruction. Two patients had significant aortic regurgitation due to aortic valve prolapse.

Conclusion: Continuous and interrupted suture techniques are equally effective in closure of VSD. Even though residual shunt is common with continuous suture technique VSD closure, 7% cases of residual shunt occurred in interrupted suture techniques in our institutions which is statistically insignificant.

Key words: Continuous suturing technique, Gore-Tex, Interrupted suturing technique, Pericardial patch closure, Polypropylene sutures, Ventricular septal defect

INTRODUCTION

Ventricular septal defect (VSD) is the most common congenital cardiac anomaly that may occur as an isolated anomaly or as a part of complex of anomaly such as tetralogy of Fallot. Small defects may close spontaneously and may cause no significant disability in lifetime. Patients with cardiomegaly and large left to right shunts are unquestionable candidates for the operation. By operating electively, the tendency to develop pulmonary hypertension, valvulitis, and bacterial endocarditis is virtually eliminated.

MATERIALS AND METHODS

All the patients for VSD closure were done by a single experienced surgeon. All patients undergoing repair for VSD in the Department of Cardiothoracic Surgery, Government Rajaji Hospital during October 2012-December 2015 were included in the study. Patients with VSD associated with complex anomalies and muscular type II were excluded from this study. One group used continuous suture for VSD closure and the other group used interrupted techniques for VSD closure. After median sternotomy, the thymus was dissected from the pericardium. Pericardium harvested as a free graft taking care to avoid injury to the phrenic nerves. It was treated with 0.6% glutaraldehyde solution for 20 min and rinsed 3 times in 0.9% saline solution for 5 min.

Cardiopulmonary bypass was started after aorta, superior vena cava, inferior vena cava cannulation. Under moderate hypothermia, cross clamp applied, antegrade cold blood cardioplegia given. Heart arrested in diastole right atrium was opened, and the VSD was inspected.
The pericardial/Gore-Tex patch was trimmed to match the size of the VSD. The defect was closed with the pericardial patch using 4/0 or 5/0 polypropylene continuous suture, starting from the inferior margin and proceeding toward the anterosuperior margin and superiority toward the aortic valve, avoiding injury to the aortic cusps. With the second arm of the suture, the postero-inferior margin was closed up to the septal leaflet of the tricuspid valve.

The tricuspid margin of the defect was closed with a reinforcing strip of pericardium. When using interrupted sutures pledget supported interrupted mattress sutures are placed around all margins of the defect and then passed through an appropriately tailored patch, which is lowered down and tied in.

Patients with an uneventful recovery were discharged after ten days. Echocardiography was done before discharge and documented.

**Data Collection**

The information collected regarding all the selected cases were recorded on a master chart. Data analysis was done with the help of computer using epidemiological information package developed by center for disease control, Atlanta.

Using this software range, frequencies, percentages, mean standard deviations, Chi-square, and "P" values were calculated. Kruskal-Wallis Chi-square test was used to test the significance of the difference between quantitative variables. A P < 0.05 is taken to denote significant relationship.

**RESULTS**

A total of 43 patients were recruited for the study. Of these, 18 had VSD repair using glutaraldehyde-treated autologous pericardial patch and 25 had VSD repair using Gore-Tex patch.

The majority of patients were in the age group of 6-10 years comprising 44% of the total study. Children under 5 years of age comprised <10% of the study group (Tables 1-3).

Most of the VSD operated were restrictive physiology. The nonrestrictive type included the VSD of outlet type (Table 4).

The most common associated anomaly was congenital mitral valve abnormality, mainly cleft mitral valve, and chordal prolapsed leading to significant mitral regurgitation requiring mitral valve repair. Right ventricular outflow tract (RVOT) obstruction was due to hypertrophied RV muscle bundle which required the division of the muscle bundle to relieve the obstruction. Two patients had significant aortic regurgitation due to aortic valve prolapse (Tables 5-10 and Graph 1).

Two patients had infective endocarditis (IE) in Gore-Tex patch group. The residual shunt was present in three patients, none of them were significant enough to warrant re-exploration and closure. One patient had nodal rhythm in Gore-Tex patch group and received temporary pacing, recovered after 1 week (Graphs 2 and 3, Tables 11-21).

**DISCUSSION**

A total of 43 patients were recruited for the study, out of these, 17 had VSD repair using continuous and 26 had repair using interrupted suture techniques.

Continuous suture technique was employed in 40% of the study group. For most of the patients in this group, pericardial patch was applied. The glutaraldehyde-treated
patch was more flexible and had better handling properties when compared to Gore-Tex patch, for ease of surgery. For the remaining patients, interrupted suture technique was used and most of them were from Gore-Tex group. They were mainly operated on by me during the study.

Patients had VSD using Gore-Tex patch and 18d patch had VSD using Goreoperatglutaraldehyde-treated autologous pericardial patch.

Congenital mitral valve abnormalities were the most common associated anomaly, mainly chordal prolapsed and cleft mitral valve with significant mitral regurgitation requiring repair. AML cleft was closed with 5-0 prolene sutures, and chordal shortening was done.12-17

The most common VSD was outlet type which comprises 51% of the study population. Perimembranous type comprises 49% in the study population.

The transarterial approach was used for most of the patients. Two patients requiring aortic valve repair were approached through aortic exposure; mitral valve repair was done through interatrial septal approach.5,7,18-20

One patient had nodal rhythm in Gore-Tex patch group with interrupted suture technique and temporary pacing was done but recovered after 6 days. Residual shunt was present in 3 patients, but none of them were significant for reexploration.

An Initiative of The Tamil Nadu Dr. M.G.R. Medical University
University Journal of Surgery and Surgical Specialties
IE was noticed in 2 patients in Gore-Tex patch group with interrupted sutures. Aortic valve prolapsed with aortic regurgitation was noted in 2 patients. Through transaortic route, they were approached and modified Trussler’s repair was done to correct the prolapsed right coronary cusp. RVOT obstruction was commonly due to RV muscle bundle hypertrophy; the obstruction was relieved by dividing the muscle bundle. Two patients had anomalous muscle bundle in RV which was excised. Patent foramen ovale was closed. One patient suffered neurological deficit in the immediate post-operative period. Definite areas of infarct were noted in the computed tomography scan of the brain, but the patient recovered successfully. The patient regained full functional recovery after a period of 2-month.

Two patients had prerenal failure in the post-operative period and conservatively managed. In the 3-day period, his renal parameters returned to normal baseline.

Two patients from the interrupted suture technique group with Gore-Tex patch had IE were successfully treated for 3 weeks with antibiotics based on culture reports.

Three patients died in the immediate post-operative period, of which two died of post-operative cardiac failure, and one died due to pulmonary hypertensive crisis of VSD.

Residual shunt was noted in three patients. No patients warranted reexploration. Two patients were from the continuous suture technique group with Gore-Tex patch, irrespective of the type.

**Limitations**

This study is limited by its nonrandomized nature and the inherent limitations of the nonrandomized studies. Only those patients who were referred for surgery and underwent surgical repair were reviewed. Indications for surgery were based on the retrospective review of the referring cardiologist clinical notes and the surgical pre-operative notes. Although the study did not address long-term follow-up of these patients, long-term survival and clinical outcomes for patients after surgical closure of isolated VSD or consistently excellent, and we would anticipate the same for this study population. In addition, we intentionally excluded patients with multiple VSDs. We recognized that patients with multiple VSDs can be a challenging group for surgical repair. However, the focus of the study was patient with isolated, single VSD.

**CONCLUSION**

Continuous and interrupted suture techniques are equally effective in closure of VSD. Even though residual shunt is common with continuous suture techniques VSD closure, 7% cases of residual shunt occurred in interrupted suture techniques in our institutions, which is statistically insignificant.

Incidence of IE is slightly higher in interrupted when compared to continuous suture techniques in our institution, could be explained by more number of pledgets used in interrupted technique which is also statistically insignificant.

Because of small number of groups included in our study, we are unable to come to conclusion and suggesting large randomized controlled study to ascertain this.
